NOTES:

Looking at the Virus Total, the behavior of this malware looks like it is most likely a trojan that uses process injection and when unzipping the file onto my computer defender said that is ransomware which gives insight into what it could be.

Following that I looked at the floss output. My hypothesis given this information, if it cannot connect with anything and if it cannot it will delete itself; then it would download something from that website and store that information into the Documents folder. Finally, it will wait to run the second the stage.

I used Detect It easy to get the basic information that it probably is not packed as it's beginner friendly, that it is compiled for 32 bit x86, it is written in C++, and that has MSVC Runtime.

From what I understand, this malware first downloads a file and places that into the documents folder then checks the download's return value, jumping to the self-deletion routine only on failure. If the file was downloaded the malware does not jump and moves to launch the payload. If the file was not downloaded the malware jumps and begins a process of deleting itself.

Starting with my dynamic analysis portion, I went into x32dbg and set breakpoints to confirm that it does reach out to the internet to get the second payload, favicon.ico. Surely enough, the FakeNet logs I can see it reaching out using Mozilla to get into the internet.

For the next step, I wanted to confirm my findings in static analysis that it does create a new file in my Desktop as well as confirmation that the ping went through.

Finally, I wanted to check that I wanted to check is if there is a "C:\Users\Public\Documents\CR433101.dat.exe" in my Documents folder. Surely enough, I found it where the static and dynamic analysis said that it was.
